# Package 'multibias'

September 23, 2024

Type Package

Title Simultaneous Multi-Bias Adjustment

Version 1.5.3

Maintainer Paul Brendel cprendel@gmail.com>

Description Quantify the causal effect of a binary exposure on a binary outcome with adjustment for multiple biases. The functions can simultaneously adjust for any combination of uncontrolled confounding, exposure/outcome misclassification, and selection bias. The underlying method generalizes the concept of combining inverse probability of selection weighting with predictive value weighting. Simultaneous multi-bias analysis can be used to enhance the validity and transparency of real-world evidence obtained from observational, longitudinal studies. Based on the work from Paul Brendel, Aracelis Torres, and Onyebuchi Arah (2023) <doi:10.1093/ije/dyad001>.

adjust\_em

#### Description

adjust\_em returns the exposure-outcome odds ratio and confidence interval, adjusted for exposure misclassification.

#### Usage

```
adjust_em(
   data,
   exposure,
   outcome,
   confounders = NULL,
   x_model_coefs,
   level = 0.95
)
```

## Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.
x_model_coefs	The regression coefficients corresponding to the model: $logit(P(X = 1)) = \delta_0 + \delta_1 X^* + \delta_2 Y + \delta_{2+j} C_j$ , where X represents the binary true exposure, $X^*$ is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters is therefore $3 + j$ .
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
adjust_em(
    evans,
    exposure = "SMK",
    outcome = "CHD",
    confounders = "HPT",
    x_model_coefs = c(qlogis(0.01), log(6), log(2), log(2))
)
```

adjust\_em\_om

Adust for exposure misclassification and outcome misclassification.

#### Description

adjust\_em\_om returns the exposure-outcome odds ratio and confidence interval, adjusted for exposure misclassification and outcome misclassification. Two different options for the bias parameters are available here: 1) parameters from separate models of X and Y (x\_model\_coefs and y\_model\_coefs) or 2) parameters from a joint model of X and Y (x1y0\_model\_coefs, x0y1\_model\_coefs, and x1y1\_model\_coefs).

#### Usage

```
adjust_em_om(
   data,
   exposure,
   outcome,
   confounders = NULL,
   x_model_coefs = NULL,
   y_model_coefs = NULL,
   x1y0_model_coefs = NULL,
   x0y1_model_coefs = NULL,
   x1y1_model_coefs = NULL,
   level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.
x_model_coefs	The regression coefficients corresponding to the model: $logit(P(X = 1)) = \delta_0 + \delta_1 X^* + \delta_2 Y^* + \delta_2 + jC_j$ , where X represents the binary true exposure, $X^*$ is the binary misclassified exposure, $Y^*$ is the binary misclassified outcome, C

4

represents the vector of measured confounders (if any), and *j* corresponds to the number of measured confounders. The number of parameters is therefore 3 + j.

y\_model\_coefs The regression coefficients corresponding to the model:  $logit(P(Y = 1)) = \beta_0 + \beta_1 X + \beta_2 Y^* + \beta_2 + jC_j$ , where Y represents the binary true exposure, X is the binary exposure, Y is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters is therefore 3 + j.

x1y0\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(X = 1, Y = 0)/P(X = 0, Y = 0)) = \gamma_{1,0} + \gamma_{1,1}X^* + \gamma_{1,2}Y^* + \gamma_{1,2+j}C_j$ , where X is the binary true exposure, Y is the binary true outcome, X\* is the binary misclassified exposure, Y\* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

x0y1\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(X = 0, U = 1)/P(X = 0, U = 0)) = \gamma_{2,0} + \gamma_{2,1}X^* + \gamma_{2,2}Y^* + \gamma_{2,2+j}C_j$ , where X is the binary true exposure, Y is the binary true outcome, X\* is the binary misclassified exposure, Y\* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

x1y1\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(X = 1, Y = 1)/P(X = 0, Y = 0)) = \gamma_{3,0} + \gamma_{3,1}X^* + \gamma_{3,2}Y^* + \gamma_{3,2+j}C_j$ , where X is the binary true exposure, Y is the binary true outcome, X\* is the binary misclassified exposure, Y\* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

level Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

# Using x\_model\_coefs and y\_model\_coefs -----

```
adjust_em_om(
  df_em_om,
  exposure = "Xstar",
  outcome = "Ystar",
  confounders = "C1",
  x_model_coefs = c(-2.15, 1.64, 0.35, 0.38),
  y_model_coefs = c(-3.10, 0.63, 1.60, 0.39)
)
# Using x1y0_model_coefs, x0y1_model_coefs, and x1y1_model_coefs ------
adjust_em_om(
  df_em_om,
  exposure = "Xstar",
  outcome = "Ystar",
  confounders = "C1"
  x1y0_model_coefs = c(-2.18, 1.63, 0.23, 0.36),
  x0y1_model_coefs = c(-3.17, 0.22, 1.60, 0.40),
  x1y1_model_coefs = c(-4.76, 1.82, 1.83, 0.72)
)
```

adjust\_em\_sel Adust for exposure misclassification and selection bias.

#### Description

adjust\_em\_sel returns the exposure-outcome odds ratio and confidence interval, adjusted for exposure misclassification and selection bias.

#### Usage

```
adjust_em_sel(
   data,
   exposure,
   outcome,
   confounders = NULL,
   x_model_coefs,
   s_model_coefs,
   level = 0.95
```

```
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.

6

#### adjust\_om

x_model_coefs	The regression coefficients corresponding to the model: $logit(P(X = 1)) = \delta_0 + \delta_1 X^* + \delta_2 Y + \delta_2 + jC_j$ , where X represents the binary true exposure, $X^*$ is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters is therefore $3 + j$ .
s_model_coefs	The regression coefficients corresponding to the model: $logit(P(S = 1)) = \beta_0 + \beta_1 X^* + \beta_2 Y + \beta_2 + jC_j$ , where S represents binary selection, $X^*$ is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters is therefore $3 + j$ .
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
adjust_em_sel(
    df_em_sel,
    exposure = "Xstar",
    outcome = "Y",
    confounders = "C1",
    x_model_coefs = c(-2.78, 1.62, 0.58, 0.34),
    s_model_coefs = c(0.04, 0.18, 0.92, 0.05)
)
```

adjust\_om

Adust for outcome misclassification.

#### Description

adjust\_om returns the exposure-outcome odds ratio and confidence interval, adjusted for outcome misclassification.

#### Usage

```
adjust_om(
   data,
   exposure,
   outcome,
   confounders = NULL,
   y_model_coefs,
   level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.
y_model_coefs	The regression coefficients corresponding to the model: $logit(P(Y = 1)) = \_delta_0 + \_delta_1X + \_delta_2Y^* + \_delta_{2+j}C_j$ , where Y represents the binary true outcome, X is the exposure, Y* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters is therefore $3 + j$ .
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
adjust_om(
  evans,
  exposure = "SMK",
  outcome = "CHD",
  confounders = "HPT",
  y_model_coefs = c(qlogis(0.01), log(1.5), log(5), log(1.5))
)
```

8

adjust\_om\_sel

#### Description

adjust\_om\_sel returns the exposure-outcome odds ratio and confidence interval, adjusted for outcome misclassification and selection bias.

#### Usage

```
adjust_om_sel(
   data,
   exposure,
   outcome,
   confounders = NULL,
   y_model_coefs,
   s_model_coefs,
   level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.
y_model_coefs	The regression coefficients corresponding to the model: $logit(P(Y = 1)) = \delta_0 + \delta_1 X + \delta_2 Y^* + \delta_{2+j} C_j$ , where Y represents the binary true outcome, X is the exposure, Y* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters is therefore $3 + j$ .
s_model_coefs	The regression coefficients corresponding to the model: $logit(P(S = 1)) = \beta_0 + \beta_1 X + \beta_2 Y^* + \beta_{2+j} C_j$ , where S represents binary selection, X is the exposure, Y* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters is therefore $3 + j$ .
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty

in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
adjust_om_sel(
    df_om_sel,
    exposure = "X",
    outcome = "Ystar",
    confounders = "C1",
    y_model_coefs = c(-3.24, 0.58, 1.59, 0.45),
    s_model_coefs = c(0.03, 0.92, 0.12, 0.05)
)
```

adjust\_sel

Adust for selection bias.

#### Description

adjust\_sel returns the exposure-outcome odds ratio and confidence interval, adjusted for selection bias.

#### Usage

```
adjust_sel(
   data,
   exposure,
   outcome,
   confounders = NULL,
   s_model_coefs,
   level = 0.95
)
```

# Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.

10

#### adjust\_uc

<pre>s_model_coefs</pre>	The regression coefficients corresponding to the model: $logit(P(S = 1)) =$
	$\beta_0 + \beta_1 X + \beta_2 Y$ , where S represents binary selection, X is the exposure, and Y
	is the outcome. The number of parameters is therefore 3.
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
adjust_sel(
  evans,
  exposure = "SMK",
  outcome = "CHD",
  confounders = "HPT",
  s_model_coefs = c(qlogis(0.25), log(0.75), log(0.75))
)
```

adjust\_uc

Adust for uncontrolled confounding.

#### Description

adjust\_uc returns the exposure-outcome odds ratio and confidence interval, adjusted for uncontrolled confounding from a binary confounder.

#### Usage

```
adjust_uc(
   data,
   exposure,
   outcome,
   confounders = NULL,
   u_model_coefs,
   level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.
u_model_coefs	The regression coefficients corresponding to the model: $logit(P(U = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 Y + \alpha_{2+j} C_j$ , where <i>U</i> is the binary unmeasured confounder, <i>X</i> is the exposure, <i>Y</i> is the outcome, <i>C</i> represents the vector of measured confounders (if any), and <i>j</i> corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .
level	Value from 0-1 representing the full range of the confidence interval. Default is $0.95$ .

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
adjust_uc(
  evans,
  exposure = "SMK",
  outcome = "CHD",
  confounders = "HPT",
  u_model_coefs = c(qlogis(0.25), log(0.5), log(2.5), log(2)),
)
```

```
adjust_uc_em
```

#### adjust\_uc\_em

#### Description

adjust\_uc\_em returns the exposure-outcome odds ratio and confidence interval, adjusted for uncontrolled confounding and exposure misclassification. Two different options for the bias parameters are available here: 1) parameters from separate models of U and X (u\_model\_coefs and x\_model\_coefs) or 2) parameters from a joint model of U and X (x1u0\_model\_coefs, x0u1\_model\_coefs, and x1u1\_model\_coefs).

#### Usage

```
adjust_uc_em(
    data,
    exposure,
    outcome,
    confounders = NULL,
    u_model_coefs = NULL,
    x_model_coefs = NULL,
    x1u0_model_coefs = NULL,
    x0u1_model_coefs = NULL,
    x1u1_model_coefs = NULL,
    level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.	
exposure	String name of the exposure variable.	
outcome	String name of the outcome variable.	
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.	
u_model_coefs	The regression coefficients corresponding to the model: $logit(P(U = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 Y$ , where U is the binary unmeasured confounder, X is the binary true exposure, and Y is the outcome. The number of parameters therefore equals 3.	
x_model_coefs	The regression coefficients corresponding to the model: $logit(P(X = 1)) = \delta_0 + \delta_1 X^* + \delta_2 Y + \delta_{2+j} C_j$ , where X represents the binary true exposure, $X^*$ is the binary misclassified exposure, Y is the outcome, and C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .	
x1u0_model_coefs		
	The regression coefficients corresponding to the model: $log(P(X = 1, U = 0)/P(X = 0, U = 0)) = \gamma_{1,0} + \gamma_{1,1}X^* + \gamma_{1,2}Y + \gamma_{1,2+j}C_j$ , where X is the binary true exposure, U is the binary unmeasured confounder, X* is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.	
x0u1_model_coefs		
	The regression coefficients corresponding to the model: $log(P(X = 0, U = 1)/P(X = 0, U = 0)) = \gamma_{2,0} + \gamma_{2,1}X^* + \gamma_{2,2}Y + \gamma_{2,2+j}C_j$ , where X is the	

	binary true exposure, $U$ is the binary unmeasured confounder, $X^*$ is the binary misclassified exposure, $Y$ is the outcome, $C$ represents the vector of measured confounders (if any), and $j$ corresponds to the number of measured confounders.		
x1u1_model_co	x1u1_model_coefs		
	The regression coefficients corresponding to the model: $log(P(X = 1, U = 1)/P(X = 0, U = 0)) = \gamma_{3,0} + \gamma_{3,1}X^* + \gamma_{3,2}Y + \gamma_{3,2+j}C_j$ , where X is the binary true exposure, U is the binary unmeasured confounder, X* is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.		
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.		

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
# Using u_model_coefs and x_model_coefs -----
adjust_uc_em(
 df_uc_em,
 exposure = "Xstar",
 outcome = "Y",
 confounders = "C1",
 u_model_coefs = c(-0.23, 0.63, 0.66),
 x_model_coefs = c(-2.47, 1.62, 0.73, 0.32)
)
adjust_uc_em(
 df_uc_em,
 exposure = "Xstar",
 outcome = "Y",
 confounders = "C1",
 x1u0_model_coefs = c(-2.82, 1.62, 0.68, -0.06),
 x0u1_model_coefs = c(-0.20, 0.00, 0.68, -0.05),
 x1u1_model_coefs = c(-2.36, 1.62, 1.29, 0.27)
)
```

adjust\_uc\_em\_sel

Adust for uncontrolled confounding, exposure misclassification, and selection bias.

#### Description

adjust\_uc\_em\_sel returns the exposure-outcome odds ratio and confidence interval, adjusted for uncontrolled confounding, exposure misclassification, and selection bias. Two different options for the bias parameters are available here: 1) parameters from separate models of U and X (u\_model\_coefs and x\_model\_coefs) or 2) parameters from a joint model of U and X (x1u0\_model\_coefs, x0u1\_model\_coefs, and x1u1\_model\_coefs). Both approaches require s\_model\_coefs.

#### Usage

```
adjust_uc_em_sel(
  data,
  exposure,
  outcome,
  confounders = NULL,
  u_model_coefs = NULL,
  x1u0_model_coefs = NULL,
  x1u0_model_coefs = NULL,
  x1u1_model_coefs = NULL,
  s_model_coefs,
  level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.
u_model_coefs	The regression coefficients corresponding to the model: $logit(P(U = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 Y$ , where U is the binary unmeasured confounder, X is the binary true exposure, and Y is the outcome. The number of parameters therefore equals 3.
x_model_coefs	The regression coefficients corresponding to the model: $logit(P(X = 1)) = \delta_0 + \delta_1 X^* + \delta_2 Y + \delta_{2+j} C_j$ , where X represents binary true exposure, $X^*$ is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .

x1u0\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(X = 1, U = 0)/P(X = 0, U = 0)) = \gamma_{1,0} + \gamma_{1,1}X^* + \gamma_{1,2}Y + \gamma_{1,2+j}C_j$ , where X is the binary true exposure, U is the binary unmeasured confounder, X\* is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

x0u1\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(X = 0, U = 1)/P(X = 0, U = 0)) = \gamma_{2,0} + \gamma_{2,1}X^* + \gamma_{2,2}Y + \gamma_{2,2+j}C_j$ , where X is the binary true exposure, U is the binary unmeasured confounder, X\* is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

x1u1\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(X = 1, U = 1)/P(X = 0, U = 0)) = \gamma_{3,0} + \gamma_{3,1}X^* + \gamma_{3,2}Y + \gamma_{3,2+j}C_j$ , where X is the binary true exposure, U is the binary unmeasured confounder, X\* is the binary misclassified exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

- s\_model\_coefs The regression coefficients corresponding to the model:  $logit(P(S = 1)) = \beta_0 + \beta_1 X^* + \beta_2 Y + \beta_{2+j} C_j$ , where *S* represents binary selection,  $X^*$  is the binary misclassified exposure, *Y* is the outcome, *C* represents the vector of measured confounders (if any), and *j* corresponds to the number of measured confounders. The number of parameters therefore equals 3 + j.
- level Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
# Using u_model_coefs, x_model_coefs, s_model_coefs ------
adjust_uc_em_sel(
    df_uc_em_sel,
    exposure = "Xstar",
    outcome = "Y",
    confounders = c("C1", "C2", "C3"),
    u_model_coefs = c(-0.32, 0.59, 0.69),
```

#### adjust\_uc\_om

```
x_model_coefs = c(-2.44, 1.62, 0.72, 0.32, -0.15, 0.85),
s_model_coefs = c(0.00, 0.26, 0.78, 0.03, -0.02, 0.10)
)
# Using x1u0_model_coefs, x0u1_model_coefs, x1u1_model_coefs, s_model_coefs
adjust_uc_em_sel(
    df_uc_em_sel,
    exposure = "Xstar",
    outcome = "Y",
    confounders = c("C1", "C2", "C3"),
    x1u0_model_coefs = c(-2.78, 1.62, 0.61, 0.36, -0.27, 0.88),
    x0u1_model_coefs = c(-2.78, 1.62, 0.61, 0.36, -0.27, 0.88),
    x0u1_model_coefs = c(-2.36, 1.62, 1.29, 0.25, -0.06, 0.74),
    s_model_coefs = c(0.00, 0.26, 0.78, 0.03, -0.02, 0.10)
)
```

adjust\_uc\_om

Adust for uncontrolled confounding and outcome misclassification.

#### Description

adjust\_uc\_om returns the exposure-outcome odds ratio and confidence interval, adjusted for uncontrolled confounding and outcome misclassification. Two different options for the bias parameters are available here: 1) parameters from separate models of U and Y (u\_model\_coefs and y\_model\_coefs) or 2) parameters from a joint model of U and Y (u1y0\_model\_coefs, u0y1\_model\_coefs, and u1y1\_model\_coefs).

#### Usage

```
adjust_uc_om(
   data,
   exposure,
   outcome,
   confounders = NULL,
   u_model_coefs = NULL,
   u1y0_model_coefs = NULL,
   u0y1_model_coefs = NULL,
   u1y1_model_coefs = NULL,
   level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.

- confounders String name(s) of the confounder(s). A maximum of three confounders is allowed.
- u\_model\_coefs The regression coefficients corresponding to the model:  $logit(P(U = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 Y$ , where U is the binary unmeasured confounder, X is the exposure, Y is the binary true outcome. The number of parameters therefore equals 3.
- y\_model\_coefs The regression coefficients corresponding to the model:  $logit(P(Y = 1)) = \delta_0 + \delta_1 X + \delta_2 Y^* + \delta_{2+j} C_j$ , where Y represents binary true outcome, X is the exposure, Y\* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals 3 + j.

u1y0\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(U = 1, Y = 0)/P(U = 0, Y = 0)) = \gamma_{1,0} + \gamma_{1,1}X + \gamma_{1,2}Y^* + \gamma_{1,2+j}C_j$ , where U is the binary unmeasured confounder, Y is the binary true outcome, X is the exposure,  $Y^*$  is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

u0y1\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(U = 0, Y = 1)/P(U = 0, Y = 0)) = \gamma_{2,0} + \gamma_{2,1}X + \gamma_{2,2}Y^* + \gamma_{2,2+j}C_j$ , where U is the binary unmeasured confounder, Y is the binary true outcome, X is the exposure,  $Y^*$  is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

u1y1\_model\_coefs

The regression coefficients corresponding to the model:  $log(P(U = 1, Y = 1)/P(U = 0, Y = 0)) = \gamma_{3,0} + \gamma_{3,1}X + \gamma_{3,2}Y^* + \gamma_{3,2+j}C_j$ , where U is the binary unmeasured confounder, Y is the binary true outcome, X is the exposure,  $Y^*$  is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders.

level Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### adjust\_uc\_om\_sel

#### Examples

```
# Using u_model_coefs and y_model_coefs -----
adjust_uc_om(
 df_uc_om,
 exposure = "X",
 outcome = "Ystar"
 confounders = "C1",
 u_model_coefs = c(-0.22, 0.61, 0.70),
 y_model_coefs = c(-2.85, 0.73, 1.60, 0.38)
)
adjust_uc_om(
 df_uc_om,
 exposure = "X",
 outcome = "Ystar",
 confounders = "C1",
 uly0_model_coefs = c(-0.19, 0.61, 0.00, -0.07),
 u0y1_model_coefs = c(-3.21, 0.60, 1.60, 0.36),
 u1y1_model_coefs = c(-2.72, 1.24, 1.59, 0.34)
)
```

adjust\_uc\_om\_sel

Adust for uncontrolled confounding, outcome misclassification, and selection bias.

#### Description

adjust\_uc\_om\_sel returns the exposure-outcome odds ratio and confidence interval, adjusted for uncontrolled confounding, outcome misclassification, and selection bias. Two different options for the bias parameters are available here: 1) parameters from separate models of U and Y (u\_model\_coefs and y\_model\_coefs) or 2) parameters from a joint model of U and Y (u1y0\_model\_coefs, u0y1\_model\_coefs, and u1y1\_model\_coefs). Both approaches require s\_model\_coefs.

#### Usage

```
adjust_uc_om_sel(
    data,
    exposure,
    outcome,
    confounders = NULL,
    u_model_coefs = NULL,
    u@y1_model_coefs = NULL,
    u1y0_model_coefs = NULL,
    u1y1_model_coefs = NULL,
    s_model_coefs,
    level = 0.95
)
```

### Arguments

data	Dataframe for analysis.	
exposure	String name of the exposure variable.	
outcome	String name of the outcome variable.	
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.	
u_model_coefs	The regression coefficients corresponding to the model: $logit(P(U = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 Y$ , where U is the binary unmeasured confounder, X is the exposure, and Y is the binary true outcome. The number of parameters therefore equals 3.	
y_model_coefs	The regression coefficients corresponding to the model: $logit(P(Y = 1)) = \delta_0 + \delta_1 X + \delta_2 Y^* + \delta_{2+j} C_j$ , where Y represents binary true outcome, X is the exposure, Y* is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .	
u0y1_model_coefs		
	The regression coefficients corresponding to the model: $log(P(U = 0, Y = 1)/P(U = 0, Y = 0)) = \gamma_{2,0} + \gamma_{2,1}X + \gamma_{2,2}Y^* + \gamma_{2,2+j}C_j$ , where U is the binary unmeasured confounder, Y is the binary true outcome, X is the exposure, $Y^*$ is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .	
u1y0_model_coefs		
	The regression coefficients corresponding to the model: $log(P(U = 1, Y = 0)/P(U = 0, Y = 0)) = \gamma_{1,0} + \gamma_{1,1}X + \gamma_{1,2}Y^* + \gamma_{1,2+j}C_j$ , where U is the binary unmeasured confounder, Y is the binary true outcome, X is the exposure, $Y^*$ is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .	
u1y1_model_coe	fs	
	The regression coefficients corresponding to the model: $log(P(U = 1, Y = 1)/P(U = 0, Y = 0)) = \gamma_{3,0} + \gamma_{3,1}X + \gamma_{3,2}Y^* + \gamma_{3,2+j}C_j$ , where U is the binary unmeasured confounder, Y is the binary true outcome, X is the exposure, $Y^*$ is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .	
s_model_coefs	The regression coefficients corresponding to the model: $logit(P(S = 1)) = \beta_0 + \beta_1 X + \beta_2 Y^* + \beta_{2+j} C_j$ , where S represents binary selection, X is the exposure, $Y^*$ is the binary misclassified outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .	
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.	

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
# Using u_model_coefs, y_model_coefs, s_model_coefs ------
adjust_uc_om_sel(
 df_uc_om_sel,
 exposure = "X",
 outcome = "Ystar"
 confounders = c("C1", "C2", "C3"),
 u_model_coefs = c(-0.32, 0.59, 0.69),
 y_model_coefs = c(-2.85, 0.71, 1.63, 0.40, -0.85, 0.22),
 s_model_coefs = c(0.00, 0.74, 0.19, 0.02, -0.06, 0.02)
)
# Using u1y0_model_coefs, u0y1_model_coefs, u1y1_model_coefs, s_model_coefs
adjust_uc_om_sel(
 df_uc_om_sel,
 exposure = "X"
 outcome = "Ystar",
 confounders = c("C1", "C2", "C3"),
 u1y0_model_coefs = c(-0.20, 0.62, 0.01, -0.08, 0.10, -0.15),
 u0y1_model_coefs = c(-3.28, 0.63, 1.65, 0.42, -0.85, 0.26),
 u1y1_model_coefs = c(-2.70, 1.22, 1.64, 0.32, -0.77, 0.09),
 s_model_coefs = c(0.00, 0.74, 0.19, 0.02, -0.06, 0.02)
)
```

adjust\_uc\_sel Adust for uncontrolled confounding and selection bias.

#### Description

adjust\_uc\_sel returns the exposure-outcome odds ratio and confidence interval, adjusted for uncontrolled confounding and exposure misclassification.

#### Usage

```
adjust_uc_sel(
   data,
   exposure,
   outcome,
   confounders = NULL,
   u_model_coefs,
   s_model_coefs,
   level = 0.95
)
```

#### Arguments

data	Dataframe for analysis.
exposure	String name of the exposure variable.
outcome	String name of the outcome variable.
confounders	String name(s) of the confounder(s). A maximum of three confounders is allowed.
u_model_coefs	The regression coefficients corresponding to the model: $logit(P(U = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 Y + \alpha_{2+j} C_j$ , where U is the binary unmeasured confounder, X is the exposure, Y is the outcome, C represents the vector of measured confounders (if any), and j corresponds to the number of measured confounders. The number of parameters therefore equals $3 + j$ .
s_model_coefs	The regression coefficients corresponding to the model: $logit(P(S = 1)) = \beta_0 + \beta_1 X + \beta_2 Y$ , where <i>S</i> represents binary selection, <i>X</i> is the exposure, and <i>Y</i> is the outcome. The number of parameters therefore equals 3.
level	Value from 0-1 representing the full range of the confidence interval. Default is 0.95.

#### Details

Values for the regression coefficients can be applied as fixed values or as single draws from a probability distribution (ex: rnorm(1, mean = 2, sd = 1)). The latter has the advantage of allowing the researcher to capture the uncertainty in the bias parameter estimates. To incorporate this uncertainty in the estimate and confidence interval, this function should be run in loop across bootstrap samples of the dataframe for analysis. The estimate and confidence interval would then be obtained from the median and quantiles of the distribution of odds ratio estimates.

#### Value

A list where the first item is the odds ratio estimate of the effect of the exposure on the outcome and the second item is the confidence interval as the vector: (lower bound, upper bound).

#### Examples

```
adjust_uc_sel(
    df_uc_sel,
```

22

#### df\_em

```
exposure = "X",
outcome = "Y",
confounders = c("C1", "C2", "C3"),
u_model_coefs = c(-0.19, 0.61, 0.72, -0.09, 0.10, -0.15),
s_model_coefs = c(-0.01, 0.92, 0.94)
```

df\_em

Simulated data with exposure misclassification

#### Description

Data containing one source of bias, three known confounders, and 100,000 observations. This data is obtained from df\_emc\_source by removing the column X. The resulting data corresponds to what a researcher would see in the real-world: a misclassified exposure, Xstar, and no data on the true exposure. As seen in df\_emc\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_em

#### Format

A dataframe with 100,000 rows and 5 columns:

**Xstar** misclassified exposure, 1 = present and 0 = absent

**Y** outcome, 1 =present and 0 =absent

C1 1st confounder, 1 = present and 0 = absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_em\_om

Simulated data with exposure misclassification and outcome misclassification

#### Description

Data containing two sources of bias, three known confounders, and 100,000 observations. This data is obtained from df\_emc\_omc\_source by removing the columns X and Y. The resulting data corresponds to what a researcher would see in the real-world: a misclassified exposure, *Xstar*, and a misclassified outcome, *Ystar*. As seen in df\_em\_om\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_em\_om

#### Format

A dataframe with 100,000 rows and 5 columns:

**Xstar** misclassified exposure, 1 =present and 0 =absent

**Ystar** misclassified outcome, 1 = present and 0 = absent

C1 1st confounder, 1 = present and 0 = absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_em\_om\_source Data source for df\_em\_om

#### Description

Data with complete information on the two sources of bias, three known confounders, and 100,000 observations. This data is used to derive df\_em\_om and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_em\_om. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_em\_om\_source

#### Format

A dataframe with 100,000 rows and 7 columns:

**X** true exposure, 1 =present and 0 =absent

**Y** outcome, 1 =present and 0 =absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

**Xstar** misclassified exposure, 1 = present and 0 = absent

**Ystar** misclassified outcome, 1 = present and 0 = absent

df\_em\_sel

#### Description

Data containing two sources of bias, three known confounders, and 100,000 observations. This data is obtained by sampling with replacement with probability = S from df\_em\_sel\_source then removing the columns X and S. The resulting data corresponds to what a researcher would see in the real-world: a misclassified exposure, *Xstar*, and missing data for those not selected into the study (*S*=0). As seen in df\_em\_sel\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_em\_sel

#### Format

A dataframe with 100,000 rows and 5 columns:

**Xstar** misclassified exposure, 1 =present and 0 =absent

**Y** outcome, 1 =present and 0 =absent

C1 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_em\_sel\_source Data source for df\_em\_sel

#### Description

Data with complete information on the two sources of bias, three known confounders, and 100,000 observations. This data is used to derive df\_em\_sel and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_em\_sel. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_em\_sel\_source

26

A dataframe with 100,000 rows and 7 columns:

**X** true exposure, 1 =present and 0 =absent

**Y** outcome, 1 =present and 0 =absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

**Xstar** misclassified exposure, 1 =present and 0 =absent

**S** selection, 1 = selected into the study and 0 = not selected into the study

df\_em\_source

Data source for df\_em

#### Description

Data with complete information on one sources of bias, three known confounders, and 100,000 observations. This data is used to derive df\_em and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_em. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_em\_source

#### Format

A dataframe with 100,000 rows and 6 columns:

**X** exposure, 1 =present and 0 =absent

**Y** true outcome, 1 = present and 0 = absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

**Xstar** misclassified exposure, 1 =present and 0 =absent

#### Description

Data containing one source of bias, three known confounders, and 100,000 observations. This data is obtained from df\_om\_source by removing the column *Y*. The resulting data corresponds to what a researcher would see in the real-world: a misclassified outcome, *Ystar*, and no data on the true outcome. As seen in df\_om\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_om

#### Format

A dataframe with 100,000 rows and 5 columns:

**X** exposure, 1 =present and 0 =absent

**Ystar** misclassified outcome, 1 = present and 0 = absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_om\_sel

Simulated data with outcome misclassification and selection bias

#### Description

Data containing two sources of bias, a known confounder, and 100,000 observations. This data is obtained by sampling with replacement with probability = S from df\_om\_sel\_source then removing the columns Y and S. The resulting data corresponds to what a researcher would see in the real-world: a misclassified outcome, *Ystar*, and missing data for those not selected into the study (S=0). As seen in df\_om\_sel\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_om\_sel

A dataframe with 100,000 rows and 5 columns:

**X** exposure, 1 =present and 0 =absent

Ystar misclassified outcome, 1 = present and 0 = absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_om\_sel\_source Data source for df\_om\_sel

#### Description

Data with complete information on the two sources of bias, a known confounder, and 100,000 observations. This data is used to derive df\_om\_sel and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_om\_sel. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_om\_sel\_source

#### Format

A dataframe with 100,000 rows and 7 columns:

**X** exposure, 1 =present and 0 =absent

**Y** true outcome, 1 = present and 0 = absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

**Ystar** misclassified outcome, 1 = present and 0 = absent

**S** selection, 1 = selected into the study and 0 = not selected into the study

df\_om\_source

#### Description

Data with complete information on one sources of bias, three known confounders, and 100,000 observations. This data is used to derive df\_om and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_om. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_om\_source

#### Format

A dataframe with 100,000 rows and 6 columns:

- **X** exposure, 1 =present and 0 =absent
- **Y** true outcome, 1 =present and 0 =absent

C1 1st confounder, 1 = present and 0 = absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

**Ystar** misclassified outcome, 1 = present and 0 = absent

df\_sel

Simulated data with selection bias

#### Description

Data containing one source of bias, three known confounders, and 100,000 observations. This data is obtained by sampling with replacement with probability = S from df\_sel\_source then removing the S column. The resulting data corresponds to what a researcher would see in the real-world: missing data for those not selected into the study (S=0). As seen in df\_sel\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_sel

A dataframe with 100,000 rows and 5 columns:

**X** exposure, 1 =present and 0 =absent

**Y** outcome, 1 =present and 0 =absent

- C1 1st confounder, 1 = present and 0 = absent
- C2 2nd confounder, 1 = present and 0 = absent
- C3 3rd confounder, 1 = present and 0 = absent

df\_sel\_source Data source for df\_sel

#### Description

Data with complete information on study selection, three known confounders, and 100,000 observations. This data is used to derive df\_sel and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_sel. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_sel\_source

#### Format

A dataframe with 100,000 rows and 6 columns:

- **X** true exposure, 1 =present and 0 =absent
- **Y** outcome, 1 =present and 0 =absent
- C1 1st confounder, 1 = present and 0 = absent
- C2 2nd confounder, 1 = present and 0 = absent
- C3 3rd confounder, 1 = present and 0 = absent
- **S** selection, 1 = selected into the study and 0 = not selected into the study

df\_uc

#### Description

Data containing one source of bias, three known confounders, and 100,000 observations. This data is obtained from df\_uc\_source by removing the column U. The resulting data corresponds to what a researcher would see in the real-world: information on known confounders (*C1*, *C2*, and *C3*), but not for confounder U. As seen in df\_uc\_source, the true, unbiased exposure-outcome effect estimate = 2.

#### Usage

df\_uc

#### Format

A dataframe with 100,000 rows and 7 columns:

**X\_bi** binary exposure, 1 =present and 0 =absent

X\_cont continuous exposure

**Y\_bi** binary outcome corresponding to exposure  $X_bi$ , 1 = present and 0 = absent

**Y\_cont** continuous outcome corresponding to exposure *X\_cont* 

C1 1st confounder, 1 = present and 0 = absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_uc\_em

Simulated data with uncontrolled confounding and exposure misclassification

#### Description

Data containing two sources of bias, three known confounders, and 100,000 observations. This data is obtained from df\_uc\_em\_source by removing the columns X and U. The resulting data corresponds to what a researcher would see in the real-world: a misclassified exposure, *Xstar*, and missing data on a confounder U. As seen in df\_uc\_em\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_em

32

A dataframe with 100,000 rows and 5 columns:

**Xstar** misclassified exposure, 1 =present and 0 =absent

**Y** outcome, 1 = present and 0 = absent

C1 1st confounder, 1 = present and 0 = absent

**C2** 2nd confounder, 1 =present and 0 =absent

C3 3rd confounder, 1 = present and 0 = absent

df\_uc\_em\_sel

Simulated data with uncontrolled confounding, exposure misclassification, and selection bias

#### Description

Data containing three sources of bias, three known confounders, and 100,000 observations. This data is obtained by sampling with replacement with probability = S from df\_uc\_em\_sel\_source then removing the columns X, U, and S. The resulting data corresponds to what a researcher would see in the real-world: a misclassified exposure, *Xstar*; missing data on a confounder U; and missing data for those not selected into the study (S=0). As seen in df\_uc\_em\_sel\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_em\_sel

#### Format

A dataframe with 100,000 rows and 5 columns:

**Xstar** misclassified exposure, 1 = present and 0 = absent

**Y** outcome, 1 =present and 0 =absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_uc\_em\_sel\_source Data source for df\_uc\_em\_sel

#### Description

Data with complete information on the three sources of bias, three known confounders, and 100,000 observations. This data is used to derive df\_uc\_em\_sel and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_uc\_em\_sel. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3 + \alpha_5 U$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_em\_sel\_source

#### Format

A dataframe with 100,000 rows and 8 columns:

- **X** true exposure, 1 =present and 0 =absent
- **Y** outcome, 1 =present and 0 =absent
- C1 1st confounder, 1 = present and 0 = absent

C2 2nd confounder, 1 = present and 0 = absent

- C3 3rd confounder, 1 = present and 0 = absent
- U unmeasured confounder, 1 = present and 0 = absent
- Xstar misclassified exposure, 1 = present and 0 = absent
- **S** selection, 1 = selected into the study and 0 = not selected into the study

df\_uc\_em\_source Data source for df\_uc\_em

#### Description

Data with complete information on the two sources of bias, a known confounder, and 100,000 observations. This data is used to derive df\_uc\_em and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_uc\_em. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 U$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_em\_source

A dataframe with 100,000 rows and 7 columns:

**X** true exposure, 1 =present and 0 =absent

**Y** outcome, 1 =present and 0 =absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

**U** unmeasured confounder, 1 = present and 0 = absent

**Xstar** misclassified exposure, 1 =present and 0 =absent

df\_uc\_om

Simulated data with uncontrolled confounding and outcome misclassification

#### Description

Data containing two sources of bias, three known confounders, and 100,000 observations. This data is obtained from df\_uc\_om\_source by removing the columns Y and U. The resulting data corresponds to what a researcher would see in the real-world: a misclassified outcome, *Ystar*, and missing data on the binary confounder U. As seen in df\_uc\_omc\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_om

#### Format

A dataframe with 100,000 rows and 5 columns:

**X** exposure, 1 =present and 0 =absent

**Ystar** misclassified outcome, 1 =present and 0 =absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_uc\_om\_sel

Simulated data with uncontrolled confounding, outcome misclassification, and selection bias

#### Description

Data containing three sources of bias, three known confounders, and 100,000 observations. This data is obtained by sampling with replacement with probability = S from df\_uc\_om\_sel\_source then removing the columns Y, U, and S. The resulting data corresponds to what a researcher would see in the real-world: a misclassified outcome, *Ystar*; missing data on a confounder U; and missing data for those not selected into the study (S=0). As seen in df\_uc\_om\_sel\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_om\_sel

#### Format

A dataframe with 100,000 rows and 5 columns:

**X** exposure, 1 =present and 0 =absent

Ystar misclassified outcome, 1 = present and 0 = absent

C1 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

df\_uc\_om\_sel\_source Data source for df\_uc\_om\_sel

#### Description

Data with complete information on the three sources of bias, three known confounders, and 100,000 observations. This data is used to derive df\_uc\_om\_sel and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_uc\_om\_sel. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3 + \alpha_5 U$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_om\_sel\_source

A dataframe with 100,000 rows and 8 columns:

**X** exposure, 1 =present and 0 =absent

**Y** true outcome, 1 =present and 0 =absent

C1 1st confounder, 1 = present and 0 = absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

U unmeasured confounder, 1 = present and 0 = absent

**Ystar** misclassified outcome, 1 = present and 0 = absent

**S** selection, 1 = selected into the study and 0 = not selected into the study

df\_uc\_om\_source Data source for df\_uc\_om

#### Description

Data with complete information on the two sources of bias, three known confounders, and 100,000 observations. This data is used to derive df\_uc\_om and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_uc\_om. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 U$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_om\_source

#### Format

A dataframe with 100,000 rows and 7 columns:

**X** exposure, 1 =present and 0 =absent

**Y** outcome, 1 =present and 0 =absent

**C1** 1st confounder, 1 =present and 0 =absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

**U** unmeasured confounder, 1 = present and 0 = absent

Ystar misclassified outcome, 1 = present and 0 = absent

df\_uc\_sel

#### Description

Data containing two sources of bias, three known confounders, and 100,000 observations. This data is obtained by sampling with replacement with probability = S from df\_uc\_sel\_source then removing the columns U and S. The resulting data corresponds to what a researcher would see in the real-world: missing data on confounder U; and missing data for those not selected into the study (S=0). As seen in df\_uc\_sel\_source, the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_sel

#### Format

A dataframe with 100,000 rows and 5 columns:

- **X** exposure, 1 =present and 0 =absent
- **Y** outcome, 1 =present and 0 =absent
- C1 1st confounder, 1 =present and 0 =absent
- C2 2nd confounder, 1 = present and 0 = absent
- C3 3rd confounder, 1 = present and 0 = absent

df\_uc\_sel\_source Data source for df\_uc\_sel

#### Description

Data with complete information on the two sources of bias, a known confounder, and 100,000 observations. This data is used to derive df\_uc\_sel and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_uc\_sel. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3 + \alpha_5 U$  shows that the true, unbiased exposure-outcome odds ratio = 2.

#### Usage

df\_uc\_sel\_source

#### Format

A dataframe with 100,000 rows and 7 columns:

- **X** true exposure, 1 =present and 0 =absent
- **Y** outcome, 1 =present and 0 =absent
- C1 1st confounder, 1 = present and 0 = absent
- C2 2nd confounder, 1 = present and 0 = absent
- C3 3rd confounder, 1 = present and 0 = absent
- U unmeasured confounder, 1 = present and 0 = absent
- **S** selection, 1 = selected into the study and 0 = not selected into the study

df\_uc\_source Data source for df\_uc

#### Description

Data with complete information on one source of bias, three known confounders, and 100,000 observations. This data is used to derive df\_uc and can be used to obtain bias parameters for purposes of validating the simultaneous multi-bias adjustment method with df\_uc. With this source data, the fitted regression  $logit(P(Y = 1)) = \alpha_0 + \alpha_1 X + \alpha_2 C1 + \alpha_3 C2 + \alpha_4 C3 + \alpha_5 U$  shows that the true, unbiased exposure-outcome effect estimate = 2 when:

- 1. g = logit,  $Y = Y_bi$ , and  $X = X_bi$  or
- 2.  $g = identity, Y = Y\_cont, X = X\_cont.$

#### Usage

df\_uc\_source

#### Format

A dataframe with 100,000 rows and 8 columns:

**X\_bi** binary exposure, 1 = present and 0 = absent

X\_cont continuous exposure

**Y\_bi** binary outcome corresponding to exposure  $X_{bi}$ , 1 = present and 0 = absent

**Y\_cont** continuous outcome corresponding to exposure X\_cont

C1 1st confounder, 1 = present and 0 = absent

C2 2nd confounder, 1 = present and 0 = absent

C3 3rd confounder, 1 = present and 0 = absent

U uncontrolled confounder, 1 =present and 0 =absent

evans

#### Description

Data from a cohort study in which white males in Evans County were followed for 7 years, with coronary heart disease as the outcome of interest.

#### Usage

evans

#### Format

A dataframe with 609 rows and 9 columns:

**ID** subject identifiction

**CHD** outcome variable; 1 = coronary heart disease

AGE age (in years)

CHL cholesterol, mg/dl

**SMK** 1 = subject has ever smoked

**ECG** 1 = presence of electrocardiogram abnormality

DBP diastolic blood pressure, mmHg

SBP systolic blood pressure, mmHg

**HPT** 1 = SBP greater than or equal to 160 or DBP greater than or equal to 95
