## 1 Introduction

Structural causal models (SCMs, Pearl, 2000, Chapter 5) consist in the simultaneous application of regression models to a set of variables, and, in a parametric linear formulation (linear SCMs), represent one of the prevalent methodologies for causal inference in contemporary applied sciences. Recently, Magrini *et al.* (2016) proposed an extension of linear SCMs composed of distributed-lag linear regression models (Judge *et al.*, 1985, Chapters 9-10), called *distributed-lag linear structural equation model* (DLSEM). A DLSEM accounts for temporal delays in the dependence relationships among the variables and allows to assess causal effects at different time lags.

Package **dlsem** implements inference functionalities for DLSEMs with several types of constrained lag shapes. This vignette is structured as follows. In Section 2, theory on the DLSEM is presented. In Section 3, instructions for the installation of the **dlsem** package are provided. In Section 4, the practical use of **dlsem** is illustrated through a simple impact assessment problem.

## 2 Theory

Lagged instances of one or more covariates can be included in the linear regression model to account for temporal delays in their influence on the response:

$$y_t = \beta_0 + \sum_{j=1}^J \sum_{l=0}^{L_j} \beta_{j,l} x_{j,t-l} + \epsilon_t \quad \epsilon_t \sim N(0, \sigma^2) \quad (1)$$

where  $y_t$  is the value of the response variable at time  $t$  and  $x_{j,t-l}$  is the value of the  $j$ -th covariate at  $l$  time lags before  $t$ . The set  $(\beta_{j,0}, \beta_{j,1}, \dots, \beta_{j,L_j})$  is denoted as the *lag shape* of the  $j$ -th covariate and represents its regression coefficient at different time lags.

Parameter estimation is inefficient because lagged instances of the same covariate are typically highly correlated. The Almon's polynomial lag shape (Almon, 1965) is a well-known solution to this problem, where coefficients for lagged instances of a covariate are forced to follow a polynomial of order  $P$ :

$$\beta_{j,l} = \sum_{p=0}^P \phi_p l^p \quad (2)$$

Unfortunately, the Almon's polynomial lag shape may show multiple modes and coefficients with different signs, thus entailing problems of interpretation. Constrained lag shapes (Judge *et al.*, 1985, Chapters 9-10) overcome this deficiency. Package `dlsem` includes the *endpoint-constrained quadratic* lag shape:

$$\beta_{j,l} = \begin{cases} \theta_j \left[ -\frac{4}{(b_j - a_j + 2)^2} l^2 + \frac{4(a_j + b_j)}{(b_j - a_j + 2)^2} l - \frac{4(a_j - 1)(b_j + 1)}{(b_j - a_j + 2)^2} \right] & a_j \leq l \leq b_j \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

the *quadratic decreasing* lag shape:

$$\beta_{j,l} = \begin{cases} \theta_j \frac{l^2 - 2b_j l + b_j^2}{(b_j - a_j)^2} & a_j \leq l \leq b_j \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

and the *gamma* lag shape:

$$\beta_{j,l} = \theta_j (l + 1)^{\frac{\delta_j}{1-\delta_j}} \lambda_j^l \left[ \left( \frac{\delta_j}{(\delta_j - 1) \log(\lambda_j)} \right)^{\frac{\delta_j}{1-\delta_j}} \lambda_j^{\frac{\delta_j}{(\delta_j - 1) \log(\lambda_j)} - 1} \right]^{-1} \quad (5)$$

$$0 < \delta_j < 1 \quad 0 < \lambda_j < 1$$

The endpoint-constrained quadratic lag shape is zero for a lag  $l \leq a_j - 1$  or  $l \geq b_j + 1$ , and symmetric with mode equal to  $\theta_j$  at  $(a_j + b_j)/2$ . The quadratic decreasing lag shape decreases from value  $\theta_j$  at lag  $a_j$  to value 0 at lag  $b_j$  according to a quadratic function. The gamma lag shape is positively skewed with mode equal to  $\theta_j$  at  $\frac{\delta_j}{(\delta_j - 1) \log(\lambda_j)}$ . Value  $a_j$  is denoted as the *gestation lag*, value  $b_j$  as the *lead lag*, and value  $b_j - a_j$  as the *lag width*. A static regression coefficient is obtained if  $a_j = b_j = 0$ . Since it is not expressed as a function of  $a_j$  and  $b_j$ , the gamma lag shape cannot reduce to a static regression coefficient, but values  $a_j$  and  $b_j$  can be computed through numerical approximation.

A linear regression model with constrained lag shapes is linear in parameters  $\beta_0, \theta_1, \dots, \theta_J$ , provided that the values of  $a_1, \dots, a_J, b_1, \dots, b_J$  are known. Thus, one can use ordinary least squares to estimate parameters  $\beta_0, \theta_1, \dots, \theta_J$  for several models with different values of  $a_1, \dots, a_J, b_1, \dots, b_J$ , and then select the one with the lowest Akaike Information Criterion (Akaike, 1974)<sup>1</sup>.

Structural causal models (SCMs) were developed by Pearl in the context of causal inference. They are rooted to path analysis (Wright, 1934) and simultaneous equation models (Haavelmo, 1943; Koopmans *et al.*, 1950). The basic feature of a SCM is a directed acyclic graph (DAG, see Pearl, 2000, pages 12 and following). In a DAG, variables are represented by nodes and directed edges may connect pairs of variables without creating directed cycles (Figure 1). If a variable receives an edge from another variable, the latter is called *parent* of the former. A DAG encodes a factorization

<sup>1</sup>Neither the response variable nor the covariates must contain a trend in order to obtain unbiased estimates (Granger and Newbold, 1974). A reasonable procedure is to sequentially apply differentiation to all variables until the Augmented Dickey-Fuller test (Dickey and Fuller, 1981) rejects the hypothesis of unit root for all of them.

of the joint probability distribution:

$$p(V_1, \dots, V_m) = \prod_{j=1}^J p(V_j \mid \Pi_j) \quad (6)$$

where  $\Pi_j$  is the set of parents of variable  $V_j$ . As such, if some pairs of variables are not connected by an edge, the DAG implies a set of conditional independence statements (Pearl, 2000, pages 16 and following). A SCM is defined by a specification of  $p(V_j \mid \Pi_j)$  for  $j = 1, \dots, J$ . In a linear parametric formulation (linear SCM),  $p(V_j \mid \Pi_j)$  is the linear regression model where  $V_j$  is the response variable and its parents in the DAG are the covariates.

Figure 1: The directed acyclic graph of a structural causal model. The regression model applied to variable  $V_1$  has no covariates, the regression models applied to variables  $V_2$  and  $V_3$  have  $V_1$  as covariate, the regression model applied to variable  $V_4$  has  $V_2$  and  $V_3$  as covariates.

The DAG of a SCM has a causal interpretation, and a causal effect is associated to each edge, directed path or couple of nodes to represent expected changes induced by an intervention (Pearl, 2000, Section 5.3; Pearl, 2012). For a linear SCM:

- the causal effect associated to each edge in the DAG is the coefficient of the variable represented by the node originating the edge in the regression model of the variable represented by the node receiving the edge;
- the causal effect associated to a directed path is the product of the causal effects associated to each edge in the path;
- the causal effect of a variable on another is the sum of the causal effects associated to each directed path connecting the nodes representing the two variables.

In this view, each causal effect in a linear SCM represents the average change in the value of a variable induced by an intervention provoking a unit variation in the value of another variable. The causal effect of a variable on another is termed *overall* causal effect, the causal effect associated to a directed path made by a single edge is called *direct* effect, while the causal effects associated to the other directed paths are denoted as *indirect* effects.

Distributed-lag linear structural equation models (DLSEMs) are an extension of linear SCMs, where each factor of the probability distribution in Equation 6 is a distributed-lag linear regression model (Judge *et al.*, 1985, Chapters 9-10). For a DLSEM, the DAG does not explicitly include time lags, and an edge connecting two nodes implies that there is at least one time lag where the coefficient of the variable represented by the parent node in the regression model of the variable represented by the child node is non-zero. A DLSEM can be exploited to assess the causal effect of any variable to another at different time lags by extending the rules above:

- The causal effect associated to each edge in the DAG at lag  $k$  is represented by the coefficient at lag  $k$  of the variable represented by the parent node in the regression model of the variable represented by the child node.
- The causal effect associated to a directed path at lag  $k$  is computed as follows:
  1. denote the number of edges in the path as  $p$ ;
  2. enumerate all the possible  $p$ -uples of lags, one lag for each of the  $p$  edges, such that their sum is equal to  $k$ ;
  3. for each  $p$ -uple of lags:
    - for each lag in the  $p$ -uple, compute the coefficient associated to the corresponding edge at that lag;
    - compute the product of all these coefficients;
  4. sum all these products.
- The causal effect of a variable on another at lag  $k$  is represented by the sum of the causal effects at lag  $k$  associated to each directed path connecting the two variables.

A causal effect evaluated at a single lag is denoted as *instantaneous* causal effect. The *cumulative* causal effect at a prespecified lag, say  $k$ , is obtained by summing all the instantaneous causal effects for each lag up to  $k$ .

### 3 Installation

Before installing `dlsem`, you must have installed R version 2.1.0 or higher, which is freely available at <http://www.r-project.org/>.

To install the `dlsem` package, type the following in the R command prompt:

```
> install.packages("dlsem")
```

and R will automatically install the package to your system from CRAN. In order to keep your copy of `dlsem` up to date, use the command:

```
> update.packages("dlsem")
```

The latest version of `dlsem` is 2.0.

### 4 Illustrative example

The practical use of package `dlsem` is illustrated through a simple impact assessment problem denoted as “industrial development problem”. The objective is to test whether the influence through time of the number job positions in industry (proxy of the industrial development) on the amount of greenhouse gas emissions (proxy of pollution) is direct and/or mediated by the amount of private consumption. The DAG for the industrial development problem is shown in Figure 2. The analysis will be conducted on the dataset `industry`, containing simulated data for 10 imaginary regions in the period 1983–2015.

```
> data(industry)
> summary(industry)
```

	Region	Year	Population	GDP

#### 4.1 Specification of the model code

The first step to build a DLSEM with the `dlsem` package is the definition of the model code, which includes the formal specification of the regression models. The model code must be a list of formulas, one for each regression model. In each formula, the response and the covariates must be quantitative variables<sup>2</sup>, and operators `quec()`, `qdec()` and `gamma()` can be employed to specify, respectively, an endpoint-constrained quadratic, a quadratic decreasing or a gamma lag shape. Operators `quec()` and `qdec()` have three arguments: the name of the variable to which the lag shape is applied, the minimum lag with a non-zero coefficient ( $a_j$ ), and the maximum lag with a non-zero coefficient ( $b_j$ ). Operator `gamma()` has three arguments: the name of the variable to which the lag shape is applied, parameter  $\delta_j$  and parameter  $\lambda_j$ . If none of these two operators is applied to a variable, it is assumed that the coefficient associated to that variable is 0 for time lags greater than 0 (no lag shape). The group factor and exogenous variables must not be specified in the model code (see Subsection 4.3). The regression model for variables with no covariates besides the group factor and exogenous variables can be omitted from the model code (for example, one could omit the regression model for the number of job positions). In this problem, an endpoint-constrained quadratic lag shape between 0 and 15 time lags is assumed for all variables:

```

> mycode <- list(
+   Job ~ 1,
+   Consum~quec(Job,0,15),
+   Pollution~quec(Job,0,15)+quec(Consum,0,15)
+ )

```

<sup>2</sup>Qualitative variables can be included only as exogenous variables, as described in Subsection 4.3.

## 4.2 Specification of control options

The second step to build a DLSEM with the `dlsem` package is the specification of control options. Control options are distinguished into global (applied to all variables) and local (variable-specific) options. Global control options must be a named list with one or more of the following components:

- **adapt**: a logical value indicating if adaptation of lag shapes must be performed, that is parameters of lag shapes must be chosen on the basis of fit to data. Default is **FALSE**, meaning no adaptation;
- **max.gestation**: the maximum gestation lag for one or more covariates. If not provided, it is taken as equal to **max.lead** (see below);
- **max.lead**: the maximum lead lag. If not provided, it is computed accordingly to the sample size;
- **min.width**: the minimum lag width. It cannot be greater than **max.lead**. If not provided, it is taken as 0;
- **sign**: the sign (either '+' for non-negative, or '-' for non-positive) of the coefficients. If not provided, adaptation will disregard the sign of coefficients.

Local control options must be a named list with the same components above, with the difference that each component must be a named list where each component refers to a specific variable and is a vector where each element refers to a specific covariate in the regression model of that variable. As an example, the following code specifies local control options on the minimum lag width of covariate `Consum` in the regression model of variable `Pollution`, and on the sign of covariates `Job` and `Consum` in the regression model of variable `Consum`:

```
> list(  
+   min.width=list(Pollution=c(Consum=5)),  
+   sign=list(Pollution=c(Job="+",Consum="+"))  
+ )
```

If some local control options conflict with global ones, only the former are applied. In this problem, we want to perform adaptation of lag shapes for all regression models with the following constraints: (i) maximum gestation lag of 3 years, (ii) maximum lead lag of 15 years, (iii) minimum lag width of 5 years, (iv) all coefficients with non-negative sign: Control options for these constraints can be expressed in several ways. The most simple solution is to specify only global control options, as the constraints hold for all regression models:

```
> mycon_G <- list(adapt=T,max.gestation=3,max.lead=15,min.width=5,sign="+")  
> mycon_L <- list()
```

In alternative, one may specify only local control options, by repeating them for each variable:

```
> mycon_G <- list()  
> mycon_L <- list(  
+   adapt=c(Consum=T,Pollution=T),  
+   max.gestation=list(Consum=c(Job=3),Pollution=c(Job=3,Consum=3)),  
+   max.lead=list(Consum=c(Job=15),Pollution=c(Job=15,Consum=15)),  
+   min.width=list(Consum=c(Job=5),Pollution=c(Job=5,Consum=5)),  
+   sign=list(Consum=c(Job="+"),Pollution=c(Job="+",Consum="+"))  
+ )
```

or both local and global control options:

```
> mycon_G <- list(adapt=T,min.width=5)  
> mycon_L <- list(  
+   max.gestation=list(Consum=c(Job=3),Pollution=c(Job=3,Consum=3)),  
+   max.lead=list(Consum=c(Job=15),Pollution=c(Job=15,Consum=15)),  
+   sign=list(Consum=c(Job="+"),Pollution=c(Job="+",Consum="+"))  
+ )
```

### 4.3 Estimation

Once the model code and control options are specified, parameter estimation can be performed using the command `dlsem(.)`. The user can indicate a single group factor (just one) to argument `group` and one or more exogenous variables to argument `exogenous`. By indicating the group factor, one intercept for each level of the group factor will be estimated in each regression model. By indicating exogenous variables, they will be included as non-lagged covariates in each regression model, in order to eliminate spurious effects due to differences between the levels of the group factor. Each exogenous variable can be either qualitative or quantitative and its coefficient in each regression model is 0 for time lags greater than 0 (no lag). The user can decide to apply the logarithmic transformation to all strictly positive quantitative variables by setting argument `log` to `TRUE`, in order to interpret each coefficient as an elasticity (percentage increase in the value of the response variable for 1% increase in the value of a covariate). Before estimation, differentiation is performed until the hypothesis of unit root is rejected by the Augmented Dickey-Fuller test for all quantitative variables<sup>3</sup>, and missing values are imputed using the Expectation-Maximization algorithm (Dempster *et al.*, 1977). In this problem, the region is indicated as the group factor, while population and gross domestic product are indicated as exogenous variables. Also, the logarithmic transformation is requested, and global and local control options are provided to arguments `global.control` and `local.control`, respectively:

```
> mod0 <- dlsem(mycode,group="Region",exogenous=c("Population","GDP"),
+   data=industry,global.control=mycon_G,local.control=mycon_L,log=T)
```

```
Checking stationarity...
Order 1 differentiation performed
Start estimation...
Estimating regression model 1/3 (Job)
Estimating regression model 2/3 (Consum)
Estimating regression model 3/3 (Pollution)
Estimation completed
```

After the estimation, the user can display the DAG where each edge is coloured with respect to the sign of the estimated causal effect (green: positive, red: negative, light gray: not significant). The result is shown in Figure 3: the group factor and exogenous variables are omitted from the DAG.

```
> plot(mod0)
```

All causal effects result statistically significant, providing evidence that the influence of industrial development on pollution is both direct and mediated by private consumption.

The user can also request the summary of estimation:

```
> summary(mod0)

$Job

Call:
lm(formula = Job ~ Region + Population + GDP, data = industry)

Residuals:
    Min       1Q   Median       3Q      Max

The summary of estimation returns estimates of parameters  $\theta_j$  ( $j = 1, \dots, J$ ). Instead, the command `edgeCoeff(.)` can be used to obtain estimates and confidence intervals of coefficients at the relevant time lags  $\beta_{j,l}$  ( $j = 1, \dots, J$ ;  $l = 0, 1, \dots$ ):

```

## 4.4 Assessment of causal effects

Causal effects can be computed using the command `causalEff(.)`. The main arguments are the name of one or more variables generating the causal effects (argument `from`), and the name of the variable receiving the causal effects (argument `to`). Optionally, specific time lags at which causal effects must be computed can be provided to argument `lag`, otherwise all the relevant ones are considered. Also, the user can choose whether instantaneous (argument `cumul` set to `FALSE`, the default) or cumulative (argument `cumul` set to `TRUE`) causal effects must be returned. The group factor and exogenous variables cannot be indicated as starting or ending variables, and they are not involved in the computation of causal effects, but the resulting causal effects are net of their influence.

Here, the cumulative causal effect of the number of job positions on the amount of greenhouse gas emissions is requested at time lags 0, 5, 10, 15 and 20:

```
> causalEff(mod0,from="Job",to="Pollution",lag=seq(0,20,by=5),cumul=T)
```

```
$`Job*Consum*Pollution`
      estimate lower 95% upper 95%
0  0.00000000 0.00000000 0.0000000
5  0.2004099 0.1494260 0.2513939
10 0.4823530 0.3645648 0.6001413
15 0.4879546 0.3675431 0.6083661
20 0.4879546 0.3675431 0.6083661
```

```

$`Job*Pollution`
      estimate lower 95% upper 95%
0  0.0000000 0.0000000 0.0000000
5  0.4140270 0.1810801 0.6469739
10 0.6210405 0.2716201 0.9704608
15 0.6210405 0.2716201 0.9704608
20 0.6210405 0.2716201 0.9704608

$overall
      estimate lower 95% upper 95%
0  0.0000000 0.0000000 0.0000000
5  0.6144369 0.3305060 0.8983677
10 1.1033935 0.6361849 1.5706021
15 1.1089950 0.6391632 1.5788269
20 1.1089950 0.6391632 1.5788269

```

The output of command `causalEff(.)` is a list of matrices, each containing estimates and confidence intervals of the causal effect associated to each path connecting the starting variables to the ending variable at the requested time lags. Also, estimates and confidence intervals of the overall causal effect are shown in the component named `overall`.

Since the logarithmic transformation was applied to all quantitative variables, causal effects above are interpreted as elasticities, that is, for a 1% of job positions more, greenhouse gas emissions are expected to grow by 0.61% after 5 years and by 1.10% after 10 years. The influence ends before 15 years, as the cumulative causal effects after 15 and 20 years are equal. The time lag up to which the effect is non-zero can be found by running command `causalEff(.)` without providing a value to argument `lag`:

```

> causalEff(mod0,from="Job",to="Pollution",cumul=T)$overall
      estimate lower 95% upper 95%
0  0.00000000 0.00000000 0.00000000
1  0.04700422 0.02108627 0.07292217
2  0.13813067 0.06526392 0.21099741
3  0.26925259 0.13357327 0.40493191
4  0.43250887 0.22417152 0.64084623
5  0.61443689 0.33050605 0.89836772
6  0.79472770 0.43994019 1.14951521
7  0.94560369 0.53269372 1.35851366
8  1.04675592 0.59612995 1.49738190
9  1.08472178 0.62369628 1.54574727
10 1.10339351 0.63618492 1.57060209
11 1.10899503 0.63916318 1.57882687
12 1.10899503 0.63916318 1.57882687

```

The estimated lag shape associated to a path or to an overall causal effect can be displayed using the command `lagPlot(.)`. For instance, one can display the lag shape associated to each path connecting the number of job positions to the amount of greenhouse gas emissions:

```

> lagPlot(mod0,path="Job*Pollution")
> lagPlot(mod0,path="Job*Consum*Pollution")

```

or the lag shape associated to the overall causal effect of the number of job positions on the amount of greenhouse gas emissions:

```

> lagPlot(mod0,from="Job",to="Pollution")

```

The resulting graphics are shown in Figure 4.

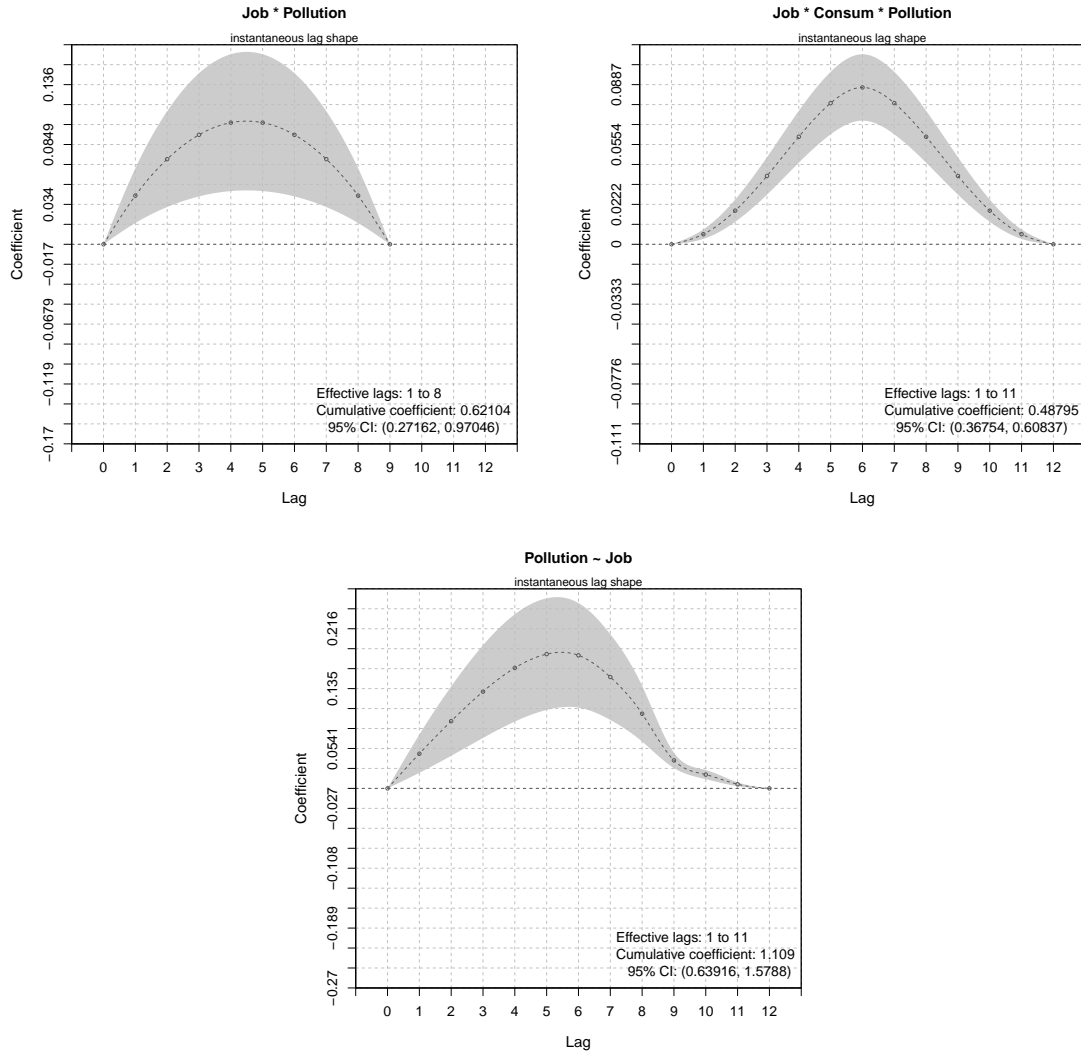

Figure 4: The estimated lag shape associated to each path connecting the number of job positions to the amount of greenhouse gas emissions (upper panels) and to the overall causal effect (lower panel). 95% confidence intervals are shown in grey.
